Abstract – In this paper, we analyse the effect of noise in a common-base amplifier working at high frequencies. Extrinsic noise is analyzed using time domain method employing techniques from stochastic calculus. Stochastic differential equations are used to obtain autocorrelation functions of the output noise voltage and other solution statistics like mean and variance. The analysis leads to important design implications for improved noise characteristics of the common-base amplifier.

Keywords – Common-Base Amplifier, Noise, Stochastic Differential Equation, Mean and Variance.

I. INTRODUCTION

The common-base amplifier is the most widely used in analog circuit design. In this paper, we shall concentrate on the noise analysis of a common-base amplifier. We analyze the effect of the noise signal on the output voltage. Noise can enter the circuit via various paths such as noise from within the amplifier (intrinsic) and the noise signal which is fed externally (extrinsic).

Circuit noise analysis is traditionally done in frequency domain. The approach is effective in cases where the circuit is linear and time invariant. But the approach is not applicable for the extrinsic noise because the system may not be either linear or time invariant due to the switching nature of the signal picked [2]. In this paper we do analysis of extrinsic noise for the common-base amplifier as shown in Fig.1.

For the stochastic model being used in this paper, the external noise is assumed to be a white Gaussian noise process. Although the assumption of a white Gaussian noise is an idealization, it may be justified because of the existence of many random input effects. According to the Central Limit Theorem, when the uncertainty is due to additive effects of many random factors, the probability distribution of such random variables is Gaussian. It may be difficult to isolate and model each factor that produces uncertainty in the circuit analysis. Therefore, the noise sources are assumed to be white with a flat power spectral density (PSD).

In this method, we shall follow a time domain approach based on solving a SDE. The method of SDEs in circuit noise analysis was used in [3] from a circuit simulation point of view. Their approach is based on linearization of SDEs about its simulated deterministic trajectory. In this paper we will use a different approach from which analytical solution to the SDE will be obtained. The analytical solution will take into account the circuit time varying nature and it will be shown that the noise becomes significant at high input signal frequencies. The main aim of our analysis is to observe the effect of noise present in the input signal on the output of the common-base amplifier.
II. ANALYSIS OF NOISE VIA SDES

Consider a common-base amplifier as shown in Fig.1 whose high-frequency equivalent is shown in Fig.2. By using approximations, the simplified equivalent circuit is shown in Fig.3. Henceforth, we analyse the circuit using SDES. From the circuit in Fig.3,

\[ i_a(t) = \frac{v_{b_e}(t)}{R_e} + c_e \frac{d}{dt} v_{b_e}(t) \]

(1)

and

\[ -i_b(t) r_{bb'} - v_{b_e}(t) - R_s \left( i_b(t) + g_m v_{b_e}(t) \right) - v_r(t) = 0 \]

so

\[ i_a(t) = \frac{v_b(t)}{R_s} - \frac{v_{b_e}(t)(1+g_m R_s)}{R_s} \]

(2)

where \( R_s = R_t + r_{bb'} \)

From equation (1) and (2), we get

\[ \frac{d v_{b_e}(t)}{dt} = k v_{b_e}(t) + \frac{1}{c_e R_s} \frac{v_{b_e}(t)}{c_e R_s} \]

(3)

where \( k = \frac{1}{c_e R_s} + \frac{1}{r_{bb'}} \)

and

\[ v_{b_e}(t) = g_s R_s v_{b_e}(t) \]

(4)

Considering \( v_{b}(t) = \sigma n(t) \), where \( n(t) \) represents Gaussian noise process and \( \sigma^2 \) is the magnitude of PSD of input noise process. Substituting \( v_{b}(t) = \sigma n(t) \) in (3), we obtain

\[ \frac{d v_{b_e}(t)}{dt} + k v_{b_e}(t) = - \frac{\sigma n(t)}{c_e R_s} \]

(5)

By multiplying both side of (5) with \( dt \), then take expectation both sides. Since the continuous-time white noise process is a generalised function, the solution is rewritten by the replacement \( n(t) dt = dW(t) \). Where \( W(t) \) is Wiener motion process, a continuous, but not differentiable process [4].

\[ E[v_{b_e}(t)] + k E[v_{b_e}(t)] dt = - \frac{\sigma^2 n(t)}{c_e R_s} \]

(6)

Using the fact that \( E[\sigma dW(t)] = 0 \), (6) results in the following:

\[ \frac{d E[v_{b_e}(t)]}{dt} + k E[v_{b_e}(t)] = 0 \]

(7)

The solution of (7) is found out to be

\[ E[v_{b_e}(t)] = c_e e^{-k t} \]

(8)

where \( c_e \) is a constant whose value depends on the initial circuit conditions. From (4) and (8) we get the mean of the output

\[ E[v_{b_e}(t)] = -g_m R_t E[v_{b_e}(t)] \]

so\[ E[v_{b_e}(t)] = -g_m R_t c_e e^{-k t} \]

(9)

Next we find the autocorrelation function which will lead us to finding the variance. For the pedagogical reasons, the autocorrelation function is obtained considering initial conditions zero. Re writing equation (3)

\[ \frac{d v_{b_e}(t)}{dt} + k v_{b_e}(t) = - \frac{\sigma n(t)}{c_e R_s} \]

(10)

Next, we consider (10) at time \( t = t_1 \) with initial conditions \( R_{b_e}, v_{b_e}(0, t_1) = E[v_{b_e}(t_1) v_{b_e}(t_2)] \big|_{t_2=0} = 0 \). Multiplying both sides of (10) with \( v_{b_e}(t_2) \) and then taking the expectation, we obtain

\[ \frac{d R_{b_e, v_{b_e}(t_1, t_2)}}{dt_2} + k R_{b_e, v_{b_e}(t_1, t_2)} = - \frac{R_{b_e, v_{b_e}(t_1, t_2)}}{c_e R_s} \]

(11)

Again, we consider (10) at time \( t = t_2 \) with initial conditions \( R_{b_e, v_{b_e}(t_1, 0)} = E[v_{b_e}(t_1) v_{b_e}(t_2)] \big|_{t_2=0} = 0 \). Multiplying both sides of (10) with \( v_{b_e}(t_1) \) and then taking the expectation, we obtain

\[ \frac{d R_{b_e, v_{b_e}(t_1, t_2)}}{dt_2} + k R_{b_e, v_{b_e}(t_1, t_2)} = - \frac{R_{b_e, v_{b_e}(t_1, t_2)}}{c_e R_s} \]

(12)

Knowing that \( R_{v_{b_e}, v_{b_e}(t_1, t_2)} = \sigma^2 \delta(t_1 - t_2) \), we find the solution of (12) as

\[ R_{v_{b_e}, v_{b_e}(t_1, t_2)} = - \frac{\sigma^2}{c_e R_s} e^{k (t_1 - t_2)} \]

(13)

Substituting the value of \( R_{v_{b_e}, v_{b_e}(t_1, t_2)} \) from (13) in (11) and taking the limit of \( t_1 \) from 0 to \( \min(t_1, t_2) \), we obtain the solution of (11) as

\[ R_{v_{b_e}, v_{b_e}(t_1, t_2)} = \frac{\sigma^2}{2k (c_e R_s)} (e^{-k (t_1 - t_2)} - e^{-k (t_1 + t_2)}) \]

(14)

For \( t_1 = t_2 = t \) in (14) we obtain the second moment of \( v_{b_e}(t) \) as \( E[v_{b_e}(t)] \)

\[ E[v_{b_e}(t)] = \frac{\sigma^2}{2k (c_e R_s)} (1 - e^{-2kt}) \]

(15)

From (4) and (15) we obtain the second moment of output as \( E[v_{b_e}^2(t)] \) which is variance in this case.

\[ E[v_{b_e}^2(t)] = (g_m R_t^2) E[v_{b_e}(t)] \]

so

\[ E[v_{b_e}^2(t)] = \frac{(g_m R_t^2) \sigma^2}{2k (c_e R_s)} (1 - e^{-2kt}) \]

(16)

III. SIMULATION RESULTS

For the simulation of the result obtained above, we use the following values for the circuit parameters:

\[ R_l = 10^4 \Omega, \quad R_s = 5 \times 10^3 \Omega, \quad r_{bb'} = 100 \Omega, \quad r_{b'e} = 1.5 \times 10^3 \Omega, \quad c_e = 2pF, \quad \sigma = 0.25, \quad g_m = 40mA/V. \]

The variation of mean with time is shown in Fig. 4, when initial conditions are nonzero, \( v_{b_e}(0) = 0.01V \). If initial conditions are zero the mean is zero all the time. The variation of variance with time is shown in Fig. 5. Initially the variance increases linearly with time then become constant.

Fig.5. Variation of variance with time
IV. CONCLUSIONS

Noise in common-base amplifier is analyzed using stochastic differential equation. Extrinsic noise is characterized by solving a SDE analytically in time domain. The solution for various solution statistics like mean and variance is obtained which can be used for design process. Suitable design methods which involve changing of device parameters are suggested to aid noise reduction and hence design the amplifier with reduced noise characteristics.
